

Fanela Planner v11

Operations usage guide

Open Fanela_Internal_Production_Planner_v11.html in your browser. This is an evolution of the v9 Stock Control edition, retaining its layout, size grids, stock history, roles, queues, Excel functions and backups.

Existing accounts and records are migrated from the previous edition when they are accessible in the same browser. If they do not appear, use a full JSON Backup from the earlier edition and restore as Admin or Operations Manager. Keep the previous file and backup until you have checked the migrated records.

Customer master and order entry

Use **Customer master records** in the order editor to save a customer's name, main contact, email, phone, billing and default dispatch addresses, dispatch method, account reference and commercial notes.

Selecting a customer copies their defaults onto the job. Change job contact, phone, email, dispatch address or dispatch method as needed: these are order snapshots. **Deliberately update customer master** is a separate confirmed action. Existing jobs keep their original snapshots even after a master record changes.

Jobs now include Customer PO, Print Name / Job Name, Order Date and Order Type alongside existing dates, priority and staff. Print names appear in lists and details. Search accepts job number, customer, PO, print name, master SKU or supplier SKU. Queues sort by dispatch deadline, priority and process date.

The product grid retains XS-5XL allocation. It now includes Supplier SKU, with the existing SKU field serving as Manufacturer / Master Product Code. Operations/Admin may enter buying costs. Director may see costs in reports; Office and department users cannot see those costs. Selling prices/tax remain available to authorised commercial users. Outstanding quantities still equal ordered minus physically received, including negative values for over-deliveries.

Artwork

The job includes proof reference, artwork version, approval status, approved-by/date and Pantone/colour notes, plus existing uploads, links, references and positions.

Operations Manager or Admin approves artwork. Other roles cannot change approved artwork. If Operations/Admin revises approved artwork, approval resets to Draft and the change is audited; approve the revised version separately. Operators see the production references and approval information relevant to their work.

Embroidery swatching

Embroidery jobs require a swatch by default. Operations/Admin may explicitly remove the requirement, with an audit entry. Older jobs gain the new swatch controls without invented historical approvals; review their requirement before starting new production.

1. Open the job from Embroidery or as Operations/Admin.
2. Create the first swatch attempt. Enter sample quantity, embroidery-file reference, thread colours, stitch count, placement, machine and notes; attach sample photos if needed.
3. Select **Start swatching**. The operator and start time are recorded.
4. Select **Complete swatch / request approval**. The completion user and time are recorded.
5. Operations/Admin approves, rejects or requests a re-swatch. A rejection/re-swatch requires a reason.
6. If rejected, create a new attempt. The old attempt, reason, photos and timestamps remain visible. An approved attempt also remains immutable; create a new attempt if another sample is needed.

Embroidery cannot start full production, add production progress or complete its stage while a required current swatch is unapproved. The queue shows waiting, swatching, awaiting approval, ready for production or in production. Stock, screens and any required swatch must all be ready before the job turns green.

Department work and audit

Department users still see only their selected stages. Active, Upcoming/Blocked and Completed views remain. The job detail shows all required department statuses for coordination, but an operator can update only their own stage.

The **Required departments** section records notes, waste and reprint quantities. Stage changes and completion record user/date/time. Completing one stage removes it from that department's Active queue, while other stages remain open. Dispatch is always required for overall completion.

The operational audit records important job/header, priority, order-line, artwork, stencil, swatch, stage, customer-master and dispatch changes. Original stock history remains a separate append-only log. Swatch attempts are retained, and general events contain before/after snapshots. Department users see audit details relevant to their work; sensitive commercial changes remain restricted.

Dispatch Management

Dispatch and Operations/Admin can edit dispatch details. Office can set the planned method/address during job entry; Director and Packing see relevant read-only information.

Method	Method-specific details
Collection	Contact, phone, date, time and collection confirmation
DPD	Consignment/tracking, parcels, weights, service, delivery instructions, contact phone/email and returned labels
Same Day	Courier, driver contact, collection time, ETA and reference
Fanela Van	Driver, route notes, planned departure and ETA

All methods retain notes, parcel count, tracking/reference and status. Changing the method in Dispatch Management saves that choice and reloads the appropriate fields; save other edits before changing method.

Record booking / collection arrangement creates a saved shipment record. **Record final dispatch/collection** records the departure, user and time. Other required stages must be finished first; Collection also needs its confirmation. After recording the final event, finish the Dispatch stage. Overall completion requires every stage and Dispatch to be complete.

Part Dispatched is available while a job remains open. Multiple shipment records can be retained. Cancellation/void is recorded against a shipment with a reason; it never erases the booking. A local cancellation does not cancel anything with a carrier.

DPD in this prototype

There is no live DPD booking, API connection or direct label-printer connection. The **BOOK & PRINT DPD LABELS** button is clearly disabled pending a backend.

Book externally with DPD, then enter the actual consignment and parcel details, confirm the external booking and attach returned PDF/image labels. Save the booking first. The saved labels can then be opened for printing and opened again for reprinting. A print request is logged, but the planner does not claim that a physical printer succeeded: use **Confirm labels printed** after checking the labels.

A PDF can contain several parcel labels; separate files can also be attached. This prototype does not generate carrier labels. If a browser or printer fails, the saved booking, tracking and label files remain available for retry. Keep attachments under 2 MB each to fit local storage.

Excel and backups

All-job, filtered, department and stock/shortage exports remain. Reports now include customer contact, PO, print name, order date, dispatch method, supplier SKU, artwork and swatch fields. Separate **Swatches**, **Shipments** and **Operational Audit** sheets support reporting. Historical quantities are snapshots, not additional goods movements: do not sum audit rows as stock transactions.

Customer/product/job templates support the new straightforward master/order fields. Imports remain add-only and checked before confirmation. Existing records are skipped. Imported artwork starts as Draft; historical swatch approvals, shipment records, photos and audit events are not reconstructed from Excel. Use full JSON Backup for complete recovery and migration. Approval and shipping decisions must be recorded in the planner.

Future system boundary

Schema version 3 retains stable customer, product, job, line and stage IDs. Jobs own address/contact/price snapshots, artwork metadata, swatch attempts and shipment records. Stock events and operational events remain separate append-only collections. The repository boundary still separates storage from Excel projections.

A future central backend must provide server-enforced login/roles, concurrent-update handling, durable audit records, shared attachment storage and managed backups. DPD credentials and Xero credentials must stay on that server. A future DPD adapter should persist the booking response and label references before submitting print work; a failed print should retry from the saved shipment. Xero remains an accounting integration over customer references and order lines, not the operational database.

This HTML edition remains browser-local. It does not synchronise records across computers or provide tamper-resistant server security. Clearing browser storage can remove local records, accounts and history. Keep regular full backups; permanent multi-user accountability requires the backend described above.
